ABSTRACT
Methods of treating malnutrition are provided, such methods not requiring the use of systemic drugs that have shown to (i) provide slow relief, (ii) cause adverse side effects, (iii) limit activities, (iv) worsen existing gastrointestinal conditions, (v) be recommended in several gastrointestinal conditions that include gastrointestinal spasms, or (vi) be recommended in the absence of diarrhea.

FIG. 2
METHODS OF TREATING MALNUTRITION

CROSS-REFERENCE TO RELATED APPLICATIONS

BACKGROUND

1. Field of the Invention

The teachings provided herein relate to methods of treating malnutrition by treating associated gastrointestinal spasms.

2. Description of Related Art

Antispasmodics can be used to prevent spasms of the stomach, intestine, uterus, or urinary bladder. Gastrointestinal spasms, for example, can be very painful. Abdominal pain and discomfort from cramping, bloating, forceful vomiting, and forceful defecation are often the result of spasmodic intestinal contractions. The problem is that there is no satisfactory treatment to relieve the pain and suffering that currently exists due to this problem. Spasms can also be treated using “anticholinergics” that counteract the effects of the neurohormone acetylcholine. The anticholinergics decrease both the movements of the stomach and intestine, and also the secretions of stomach acid and digestive enzymes. Problems with these drugs include dry mouth and dry eyes because of reduced salivation and tearing.

An example of an anticholinergic that is used to treat cramping is loperamide, an opioid-receptor agonist that slows peristalsis. As such, it is not directed to relieve cramping from spasms, per se. Moreover, loperamide crosses the blood-brain barrier and, although quickly removed from the CNS by P-glycoprotein, it can be addictive if taken with a drug that inhibits P-glycoprotein. Moreover, loperamide has several contraindications, such that it’s not recommended for use with several conditions that can include gastrointestinal spasms. For example, it is not recommended for treatment with conditions containing organisms that cross the intestinal walls, such as E. coli O157:H7 or salmonella. And, ironically, although it is often administered to alleviate abdominal pain and cramping, its adverse effects can actually include abdominal pain and bloating, nausea, vomiting and constipation. In fact, loperamide has been labeled as (a) contraindicated in patients with abdominal pain in the absence of diarrhea; (ii) not recommended in children below 24 months of age; and (iii) not recommended as the primary therapy in patients with (a) acute dysentery, which is characterized by blood in stools and high fever; (b) acute ulcerative colitis; (c) bacterial enterocolitis caused by invasive organisms including Salmonella, Shigella, and Campylobacter; or, (d) pseudomembranous colitis associated with the use of broad-spectrum antibiotics. See, for example, http://dailymed.nlm.nih.gov/dailymed/Archives/fdaDrugInfo.cfm?archive=41053, Lake Erie Medical DBA Quality Care Products LLC.

A condition of particular interest in the treatment of gastrointestinal spasms is irritable bowel syndrome (IBS), a condition afflicting an estimated 30 million people in the US and up to 700 million people worldwide. IBS is diagnosed from clinical symptoms that include abdominal pain, bloating, constipation, and diarrhea. Treatment options are based upon the predominant symptom, with diarrhea-predominant IBS receiving antidiarrheal agents, such as loperamide (IMMODYUM) and pain-predominant IBS patients receiving antispasmodic agents, such as dicyclomine HCl (BENTYL) and hyoscyamine sulfate (LEVOMPAR). The condition is generally thought to be the result of spasmodic contractions of the intestines that interfere with normal peristalsis causing blockages that lead to bloating and constipation, cause hyperperistaltic activity leading to frequent need for defecation, or a combination. Problems with loperamide are discussed above. Dicyclomine has the problem of some people sweat less, allowing the body to overheat which can cause heat prostration (fever and heat stroke). As such, anyone taking this drug should try to avoid extreme heat. Moreover, dicyclomine can also cause drowsiness and blurred or double vision, such that people who take this drug should not drive, use machines, or do anything else that might be dangerous. Hyoscyamine can also be used but, unfortunately, both dicyclomine and hyoscyamine have general side effects and, for example, can worsen gastroesophageal reflux disease. Anticholinergics, generally speaking, are also known to cause difficulty in passing urine, and children and the elderly are at a higher risk of developing such side effects.

One of skill would appreciate having a method of treating spasms, particularly gastrointestinal spasms, without having to use systemic drugs that have shown to (i) provide slow relief, (ii) cause adverse side effects, (iii) limit activities, (iv) worsen existing gastrointestinal conditions, (v) be unrecommended in several gastrointestinal conditions that include gastrointestinal spasms, and (vi) be unrecommended in the absence of diarrhea.

SUMMARY

The teachings provided herein relate to methods of treating gastrointestinal spasms. The teachings include methods of treating gastrointestinal spasms without having to use systemic drugs that have shown to (i) provide slow relief, (ii) cause adverse side effects, (iii) limit activities, (iv) worsen existing gastrointestinal conditions, (v) be unrecommended in several gastrointestinal conditions that include gastrointestinal spasms, or (vi) be unrecommended in the absence of diarrhea.

In some embodiments, the teachings are directed to a method of treating a gastrointestinal spasm in a subject, the method comprising administering an effective amount of a composition to a subject having a gastrointestinal spasm, the composition having a polyphenol combined with a reactive oxygen species. And, in some embodiments, the composition can be produced from a process including combining a polyphenol with a reactive oxygen species; selecting a desired concentration for the composition; and, diluting the composition to the desired concentration for the administering. In these embodiments, the polyphenol can have a molecular weight ranging from about 170 Daltons to about 4000 Daltons; and, the composition can relieve a gastrointestinal spasm in the subject either (i) when compared to a second subject in a control group in which the composition was not administered or (ii) when compared to a historic baseline of the symptoms present in the subject. The measurement of relief from gastrointestinal spasms can be measured using any of a variety of parameters, in some embodiments. For example, the relief of the spasm can be measured using a response selected from the group consisting of a
reduction in abdominal pain, a reduction in bloating, a reduction in forceful defecation, a reduction in forceful vomiting, a reduction in defecation urgency, a reduction in constipation, and/or a reduction in incontinence.

The polyphenol can comprise a single component, a mixture of components, or a whole extract of a plant tissue, in some embodiments. In some embodiments, the polyphenol comprises a tannin. In some embodiments, the polyphenol comprises a hydrolysable tannin, a condensed tannin, or a combination of a hydrolysable tannin and a condensed tannin. In some embodiments, the polyphenol can comprise a pseudotannin, for example, from the group consisting of gallic acid, which can be found in an extract of a rhubarb plant tissue, for example; flavan-3-ols or catechins, which can be found in an extract of acacia, catechu, cocoa, or guarana, for example; chlorogenic acid, which can be found in coffee, or mate; or, epicatechin, which can be found in cappuccina, for example. As such, it should be appreciated that, in some embodiments, the polyphenol component can comprise a flavanol or a catechin. Moreover, the polyphenol can comprises gallic acid, epigallocatechin, or a combination thereof, in some embodiments.

The reactive oxygen species can be any such species known to one of skill to have the ability to combine with the polyphenol as a composition for the uses taught herein. In some embodiments, the reactive oxygen species comprises hydrogen peroxide. And, in some embodiments, the hydrogen peroxide can be combined with the tannin at a tannin: hydrogen peroxide weight ratio that ranges from about 1:1000 to about 10:1. In some embodiments, the weight ratio of the tannin: hydrogen peroxide ranges from about 1:1 to about 1:50.

And, consistent with the above, one of skill will appreciate that the polyphenol can be combined with the reactive oxygen species as a component of a water or alcohol extract of a plant tissue. In some embodiments, the plant tissue can comprise a tannin or a pseudotannin.

One of skill reading the teachings that follow will appreciate that the concepts can extend into additional embodiments that go well-beyond a literal reading of the claims, the inventions recited by the claims, and the terms recited in the claims.

BRIEF DESCRIPTION OF THE FIGURES

FIGS. 1A-1H are photographs of the dry forms of (A) gallic acid (a model polyphenol building block) bound to hydrogen peroxide; (B) gallic acid alone; (C) tannin acid (a model polyphenol) bound to hydrogen peroxide; (D) tannic acid alone; (E) pomegranate husk extract bound to hydrogen peroxide; (F) pomegranate husk extract alone; (G) green tea extract bound to hydrogen peroxide; and (H) green tea extract alone, according to some embodiments.

FIGS. 2A and 2B show that the stability of the hydrogen peroxide in the combination is consistently, substantially greater in an aqueous solution than the stability of the hydrogen peroxide alone in the aqueous solution, according to some embodiments.

DETAILED DESCRIPTION

Methods of treating gastrointestinal spasms are provided herein. The methods include treating gastrointestinal spasms without having to use systemic drugs. Such systemic drugs have been reported to (i) provide slow relief; (ii) cause adverse side effects; (iii) limit activities; (iv) worsen existing gastrointestinal conditions; (v) be unremarked in several gastrointestinal conditions that include gastrointestinal spasms, or (vi) be unremarked in the absence of diarrhea.

In some embodiments, the method of treating a gastrointestinal spasm in a subject comprises administering an effective amount of a composition to a subject having a gastrointestinal spasm, the composition having a polyphenol combined with a reactive oxygen species. And, in some embodiments, the composition can be produced from a process including combining a polyphenol with a reactive oxygen species; selecting a desired concentration for the composition; and, diluting the composition to the desired concentration for the administering. In these embodiments, the polyphenol can have a molecular weight ranging from about 170 Daltons to about 4000 Daltons; and, the composition can relieve a gastrointestinal spasm in the subject either (i) when compared to a second subject in a control group in which the composition was not administered or (ii) when compared to a historic baseline of the symptoms present in the subject.

To provide a desired therapeutic relief, the compositions can be directed to act on tissues at a particular target site, which can be gastrointestinal tissue, in some embodiments. The term “target site” can be used to refer to a select location at which the composition acts to provide a therapeutic effect, or treatment as described herein. In some embodiments, the target site can be a tissue of any organ in which control of a spasm is desirable. Moreover, the target can include any site of action in which the phenolic compound can be site-activated by an oxidoreductase enzyme that is available at the site. The oxidoreductase enzyme can be produced endogenously by a tissue at a target site, produced endogenously by a microbe, introduced exogenously to the target site, include more than one enzyme, co-enzyme, catalyst, or cofactor, or a combination thereof. The measurement of relief from gastrointestinal spasms, for example, can be measured using any of a variety of parameters. For example, the relief of the spasm can be measured using a response selected from the group consisting of a reduction in abdominal pain, a reduction in bloating, a reduction in defecation urgency, a reduction in forceful vomiting, a reduction in defecation urgency, and/or a reduction in incontinence.

Without intending to be bound by any theory or mechanism of action, the compositions taught herein can include phenolics, for example, polyphenols. The polyphenolic compounds taught herein are selected to combine with a reactive oxygen species to form a composition that is deliverable as a stable, or substantially stable, system. In some embodiments, the compositions can include a polyphenol compound combined with hydrogen peroxide, a combination of components having an association that offers a stability and activity, both of which are offered by neither component alone. Such a composition can be delivered to a target site, for example, in a polar solution such as water or an alcohol. In some embodiments, at least a substantial amount of the hydrogen peroxide can remain bound, or otherwise associated with, and thus stable or substantially stable, with the polyphenolic compound. Moreover, in some embodiments, the composition contains no, or substantially no, unbound hydrogen peroxide. The teachings also include a pharmaceutical formulation comprising the compositions taught herein and a pharmaceutically acceptable excipient.

The terms “composition,” “compound,” “binding system,” “binding pair,” and “system” can be used interchangeably in some embodiments and, it should be appreciated that a “formulation” can comprise a composition, compound, binding system, binding pair, or system presented herein. Likewise, in some embodiments, the compositions taught herein can also be referred to as an “agent,” a “bioactive agent,” or a “supple-
ment" whether alone, in a pharmaceutically acceptable composition or formulation, and whether in a liquid or dry form. Moreover, the term "bioactivity" can refer to a treatment that occurs through the use of the compositions provided herein. One of skill will appreciate that the term "bind," "binding," "bound," "attached," "connected," "chemically attached," "chemically connected," "chemically attached," "combined," or "associated" can be used interchangeably, in some embodiments. Such terms, for example, can be used to refer to any association between the polyphenol and reactive oxygen species that has resulted in an increased stability and/or sustained activity of the composition or components in the compositions. For example, the terms can be used to describe a chemical bonding mechanism known to one of skill, such as covalent, ionic, dipole-dipole interactions, London dispersion forces, and hydrogen bonding, for example. In some embodiments, the compositions can comprise a phenolic compound sharing hydrogen bonds with reactive oxygen species, for example, such as hydrogen peroxide. In some embodiments, the phenolic compound can comprise a polyphenol that covalently binds to an amino acid or polypeptide.

One skill will appreciate that the compositions should remain stable, or at least substantially stable, until useful or activated, and that this can relate to a measure of time. Such a measure of time can include a shelf life, or a time between creation of the composition and administration of the composition, or some combination thereof. In some embodiments, the composition is stable, or substantially stable, when usable as intended within a reasonable amount of time. In some embodiments, the composition should be usable within a reasonable time from the making of the composition to the administration of the composition and, in some embodiments, the composition should have a reasonable commercial shelf life. The composition can be considered as "stable" if it loses less than 10% of its original oxidation potential, and this can be measured by comparing it's oxidation potential after making the composition to the time of administration, and this can include a reasonable shelf life, in some embodiments. In some embodiments, the composition can be considered as stable if it loses less than 5%, 3%, 2%, or 1% or less of its original oxidation potential when comparing it's oxidation potential after making the composition to the time of administration, and this can include a reasonable shelf life, in some embodiments. The composition can be considered as "substantially stable" if it loses greater than about 10% of it's original oxidation potential, as long as the composition can perform it's intended use to a reasonable degree of efficacy. The loss can be measured, as above, by measured by comparing it's oxidation potential after making the composition to the time of administration, and this can include a reasonable shelf life, in some embodiments. In some embodiments, the composition can be considered as substantially stable if a reactive oxygen species loses greater than about 12%, about 15%, about 25%, about 35%, about 45%, about 50%, about 60%, or even about 70% of it's original oxidation potential. The loss may be measured by measuring by comparing it's oxidation potential after making the composition to the time of administration, and this can include a reasonable shelf life, in some embodiments. The time to compare the oxidation potential for a measure of stability can range from about 30 minutes to about one hour, from about one hour to about 12 hours, from about 12 hours to about 1 day, from about one day to about one week, from about 1 week to about 1 month, from about 1 month to about 3 months, from about 1 month to a year, from 3 months to a year, from 3 months to 2 years, from 3 months to 3 years, greater than 3 months, greater than 6 months, greater than one year, or any time or range of times therein, stated in increments of one hour.

One of skill will appreciate that the phenolic compound used in the compositions can be any phenolic compound that functions consistent with the teachings provided herein, and there are at least several thousand such phenolic compounds known to those of skill that can be expected to function as desired. As such, the teachings provided herein can only include examples of the general concepts rather than a comprehensive listing of all possibilities and permutations of the systems that are enabled by the teachings.

The phenolic compound can be a polyphenol, and the polyphenol can comprise a single component, a mixture of components, or a whole extract of a plant tissue, in some embodiments. In some embodiments, the polyphenol comprises a tannin. In some embodiments, the polyphenol comprises a hydrolysable tannin, a condensed tannin, or a combination of a hydrolysable tannin and a condensed tannin. In some embodiments, the polyphenol can comprise a pseudotannin selected, for example, from the group consisting of gallate acid, which can be found in the extract of rubarb plant tissue, for example; flavan-3-ols or catechins, which can be found in an extract of acacia, catechu, cocoa, or guarana, for example; chlorogenic acid, which can be found in coffee, or mate, or ipecacuanha, which can be found in ipecacuanha, for example. As such, it should be appreciated that, in some embodiments, the polyphenol component can comprise a flavanol or a catechin. Moreover, the polyphenol can comprises gallic acid, epigallocate, or a combination thereof, in some embodiments.

In some embodiments, the phenolic compound has at least one aryl group, or arene moiety, and at least two polar aromatic groups, such as aromatic hydroxyl groups. In some embodiments, the polar aromatic groups can be, for example, hydroxy, amine, amide, acyl, carboxyl, or carbonyl. In some embodiments, the phenolic compound has at least two aryl groups, and at least two hydroxyl groups. In some embodiments, the phenolic compounds can be naturally occurring, such as from a plant or other natural product. And, in some embodiments, the phenolic compounds can be synthetically or semi-synthetically produced. The compounds can be simple monomers, oligomers, or polymers. The polymers can be in the class of polyphenols or polymeric phenols, where one of skill will understand that the general difference is typically that polyphenols generally do not have a repeating unit, whereas polymeric phenols do. There are exceptions, however, such that groups of polyphenols and polymeric phenols can overlap. In most embodiments, the phenolic compound used in the binding system can be any phenolic compound taught herein, or any prodrugs, codrugs, metabolites, analogs, homologues, congeners, derivatives, salts, solvates, and combinations thereof.

In some embodiments, the phenolic compounds bind to hydrogen peroxide to form a binding pair and, in some embodiments, the binding pair remains stable, or substantial stable in water. In some embodiments, the binding pair remains stable, or substantial stable in an alcohol. And, in some embodiments, the binding pair remains stable, or substantial stable in a polar solvent such as, for example, a saline solution, an aqueous emulsion, a hydrogel, and the like. In some embodiments, the phenolic compounds are polyphenols having molecular weights ranging from about 170 to about 4000 Daltons, having from about 12 to about 16 phenolic hydroxyl groups, and having from about five to about seven aromatic rings, for every about 1000 Daltons in molecular weight. In some embodiments, the phenolic compounds function to precipitate alkaloids and proteins. In some
embody, the phenolic compounds can bind to cellular receptors, amino acids, peptides, oligopeptides, polyols, saccharides, or combinations thereof. In some embodiments, the phenolic compounds have at least from about 1 to about 20 polyhydroxylated phenolic units and have at least moderate water solubility.

The term “solubility” can refer to a concentration of a solute in a solvent, for example, the phenolic compound in water. The concentration can be expressed by mass, for example, mg of the phenolic compound per kg of water at ambient temperature and pressure. This ratio of mg/kg can be used interchangeably with ppm, and ng/kg can be used interchangeably with ppb. In some embodiments, the solubility of the phenolic compound can be higher than about 500,000 ppm or less than about 1 ppm. In some embodiments, the solubility of the phenolic compound range from about 10 ppm to about 500,000 ppm, from about 10 ppm to about 100,000 ppm, from about 10 ppm to about 50,000 ppm, from about 10 ppm to about 25,000 ppm, from about 100 ppm to about 10,000 ppm, from about 100 ppm to about 100,000 ppm, from about 200 ppm to about 100,000 ppm, from about 250 ppm to about 50,000 ppm, from about 500 ppm to about 25,000 ppm, from about 250 ppm to about 10,000 ppm, or any range therein. In some embodiments, the solubility can range from about 1 g/L to about 10,000 g/L, from about 5 g/L to about 5000 g/L, from about 10 g/L to about 3000 g/L, from about 20 g/L to about 2000 g/L, from about 50 g/L to about 1000 g/L, from about 100 g/L to about 500 g/L, or any range therein. For purposes of the teachings provided herein, a compound can be considered to have a low solubility if the solubility is less than about 5 g/L, a moderate solubility if the solubility ranges from about 5 g/L to about 1000 g/L, and a high solubility if the solubility is above about 1000 g/L. In some embodiments, the phenolic compound can have a high solubility. In some embodiments, the phenolic compound can have a moderate solubility. And, in some embodiments, the phenolic compound can have a high solubility.

One of skill will appreciate that the phenolic compounds can still be useful at low solubilities in cases where the solubility is too low to form a true solution. In some embodiments the phenolic compounds can be ground into particles to form a colloidal mixture or suspension that will function consistent with the teachings provided herein. As such, liquid formulations include colloids and suspensions in some embodiments. The formulations can be a dispersed phase mixture in the form of colloidal aerosols, colloidal emulsions, colloidal foams, colloidal dispersions, or hydrogels. In some embodiments, the liquid formulations can include particles having sizes ranging, for example, from about 5 nm to about 200 nm, from about 5 nm to about 500 nm, from about 5 nm to about 750 nm, from about 50 nm to about 1 um. In some embodiments, the liquid formulations can be suspensions, in which the particle size range from about 1 um to about 10 um, from about 1 um to about 7 um, from about 1 um to about 5 um, or any range therein. In some embodiments, the liquid formulation can include particles having sizes ranging from about 1 nm to about 10 nm.

The functionality of a phenolic compound in the teachings herein can, for at least the reason of solubility, depend on molecular weight, alone or in addition to other factors discussed herein such as, for example, extent of hydroxylation, presence and location of ketone or quinone groups, and the presence of other functional groups. In some embodiments, the molecular weights of the phenolic compounds can range from about 110 Daltons to about 40,000 Daltons. In some embodiments, the molecular weights of the phenolic compounds can range from about 200 Daltons to about 20,000 Daltons, from about 300 Daltons to about 30,000 Daltons, from about 400 Daltons to about 40,000 Daltons, from about 500 Daltons to about 10,000 Daltons, from about 1000 Daltons to about 5,000 Daltons, from about 170 Daltons to about 4000 Daltons, from about 350 Daltons to about 4,000 Daltons, from about 300 Daltons to about 3,000 Daltons, from about 110 Daltons to about 2,000 Daltons, from about 200 to about 5000 Daltons, or any range or molecular weight therein in increments of 10 Daltons.

In some embodiments, the ratio of aromatic rings to molecular weight of the phenolic compounds can range from about 2 to about 10 aromatic rings for every about 1000 Daltons. In some embodiments, the ratio of aromatic rings to molecular weight of the phenolic compounds can range from about 2 to about 10 aromatic rings for every about 1000 Daltons, from about 3 to about 9 aromatic rings for every about 1000 Daltons, from about 4 to about 8 aromatic rings for every about 1000 Daltons, from about 5 to about 7 aromatic rings for every about 1000 Daltons, from about 1 to about 4 for every about 500 Daltons, from about 1 to about 3 for every about 500 Daltons, from about 2 to about 4 for every about 500 Daltons, or any amount or range therein in increments of 1 ring.

One of skill will appreciate that, in some embodiments the phenolic compounds can have, or be synthesized or otherwise designed to contain functional groups that are capable of releasably bonding to a reactive oxygen species, in a stable or substantially stable form, until either consumed or released upon bioactivation at a target site. In some embodiments, a releasable bond can include any bond other than a covalent bond. In some embodiments, a releasable bond is a hydrogen bond. As such, the phenolic compounds should be capable of forming, for example, a hydrogen bond with a reactive oxygen species upon such bioactivation. In some embodiments, the phenolic compound shares hydrogen bonding with hydrogen peroxide and is released through a bioactivation that occurs when the binding pair comes into contact with an oxidoreductase enzyme or other reducing agent. In some embodiments, the phenolic compound can have functional groups that comprise acyl, amidoo, amino, carbonyl, carboxyl, hydroxyl, or peroxyl functionality. In some embodiments, the hydrogen bond between the reactive oxygen species and the phenolic compound can include any hydrogen donor and any hydrogen acceptor having an available lone pair of electrons. In some embodiments, the hydrogen acceptor can include, for example a N, O, or F atom, or a combination thereof. In some embodiments, the phenolic compound can have such a functionality, can be derivatized to have such a functionality, can be linked to another compound having such a functionality, can be placed in a carrier having such a functionality, or some combination thereof.

In some embodiments, phenolic compounds can include simple phenols, such as those containing 6 carbons, a C6 structure, and 1 phenolic cycle, such as the benzene alcohols, examples of which include phenol, benzene diols and its isomers such as catechol, and the benzenediols. In some embodiments, phenolic compounds can include phenolic acids and aldehydes, such as those containing 7 carbons, a C6-C1 structure, and 1 phenolic cycle, examples of which include gallic acid and salicylic acids. In some embodiments, phenolic compounds can include, for example, tyrosine derivatives, and phenylacetic acids, such as those containing 8 carbons, a C6-C2 structure, and 1 phenolic cycle, examples of which include 3-octyl-6-methoxybenzylidene, tyrosol, and 3-hydroxyphenylacetic acid. In some embodiments, pheno-
nolic compounds can include hydroxycinnamic acids, phenylpropenes, chromones, such as those containing 9 carbons, a C6-C3 structure, and 1 phenolic cycle, examples of which include caffeic acid, ferulic acids, myristicin, engenol, umbelliferone, ascorbic acid, bergenon, and eugenol. In some embodiments, phenolic compounds can include naphthoquinones, such as those containing 10 carbons, a C6-C4 structure, and 1 phenolic cycle, examples of which include juglone and plumbagin. In some embodiments, phenolic compounds can include xanthones, such as those containing 13 carbons, a C6-C1-C6 structure, and 2 phenolic cycles, examples of which include resveratrol and emodin. In some embodiments, phenolic compounds can include chromones, flavones, isoflavones, and neoflavonoids, such as those containing 15 carbons, a C6-C3-C6 structure, and 2 phenolic cycles, examples of which include quercetin, myricetin, luteolin, cyanidin, and genistein. In some embodiments, phenolic compounds can include lignans and neolignans, such as those containing 18 carbons, a C6-C3-C6-C6 structure, and 2 phenolic cycles, examples of which include pinoresinol and eusiderin. In some embodiments, phenolic compounds can include biflavonoids, such as those containing 30 carbons, a (C6-C3-C6) structure, and 4 phenolic cycles, examples of which include amentoflavone. In some embodiments, phenolic compounds can include polyphenols, polyphenolic proteins, lignins, and catechol melanins, such as those containing >30 carbons. In these embodiments, the phenolic compounds can have, for example, a (C6-C3), structure, a (C6) structure, a (C6-C3-C6) structure, or some combination thereof, as well as greater than about 12 phenolic cycles. Examples of such embodiments can include, for example, the flavonols, in the class of condensed tannins.

In some embodiments, the phenolic compounds are natural phenols that can be enzymatically polymerized. Derivatives of natural phenols can also be used in some embodiments. These embodiments can include phenolic compounds having less than 12 phenolic groups, such that they can range from monophenols to oligophenols. In some embodiments, the natural phenols are found in plants, have an antioxidant activity, or a combination thereof. Examples of the natural phenols include, for example, catechol- and resorcinol-types (benzenediols) with two phenolic hydroxy groups, and pyrogallol- and phlorogluconol-types (benzenetrinets) with three hydroxy groups. Natural phenols may have heteroatom substituents other than hydroxyl groups, ether and ester linkages, carboxylic acid derivatives, or some combination thereof. In some embodiments, the natural phenols include natural phenol drugs and their derivatives. Examples of such drugs include, but are not limited to, anthraquinone drugs, flavone drugs, and flavonol drugs. Examples of anthraquinone drugs include, but are not limited to, aloe emodin, aypaurmycin, and diacerein. Examples of flavone drugs include, but are not limited to, anesotenine and hidrosmin. Examples of flavonol drugs include, but are not limited to, monoxerutin and troxerutin.

In some embodiments, the phenolic compound is a tannin, a polyphenolic phenylpropanoid, or a combination thereof. In some embodiments, the tannin is a hydrolysable tannin, a condensed tannin, or a combination thereof. Hydrolysable tannins can be found, for example, in Chinese gall, which is almost pure in that it has no or substantially no condensed tannins. Condensed tannins can be found, for example, in green tea leaf, which is also almost pure in that it has no or substantially no hydrolysable tannins.

Examples of hydrolysable tannin can include gallotannic acids, qurroctannic acids, ellagittannins, gallotannin, pentagalloyl glucose, gallohyquinaric acid, galloylshikimic acid, and punicalagin. In some embodiments, the hydrolysable tannin is a gallotannin or ellagittannin, and isomers thereof, such as isomers that can precipitate protein. Examples of gallotannins include the gallic acid esters of glucose in tannin acid (C_{6}H_{12}O_{16}) and pentagalloyl glucose (PGG), and isomers thereof, such as the isomers of PGG that function to precipitate proteins. Examples of an ellagittannin include castilin and punicalagin. In some embodiments, the tannin is a gallic acid ester having a molecular weight ranging from about 500 Daltons to about 3000 Daltons. In some embodiments, the tannin is a proanthocyanidin having a molecular weight of up to about 20,000 Daltons. In some embodiments, the hydrolysable tannins are derivatives of gallic acid and characterized by a glucose, quinic acid or shikimic acid core with its hydroxyl groups partially or totally esterified with gallic acid or ellagic acid groups. The compounds can have 3 to 12 galloyl residues but may be further oxidatively crosslinked and complex. Hydrolysable tannins can be readily synthesized, for example, to obtain a phenolic compound with a high number of polar functional groups that form multiple, stable hydrogen bonds between the tannin and hydrogen peroxide in the binding system. It should be appreciated that, while hydrolysable tannins and most condensed tannins are water soluble, some very large condensed tannins are insoluble. In some embodiments, the phenolic compound can comprise a hydrolysable tannin such as, for example, burkinabin C, castalagin, castalin, casuarinictin, chebulagin, chebulic acid, corilagin, digallic acid, ellagittannin, gallic acid, gallotannin, glucogallin, gruninuk, hexahydroxydiphenic acid, pentagalloyl glucose, punicalagin alpha, punicalagin, rhamnolagin, ellagittannin, robinin A, stenophyllinan A, stenophyllinan A, tannate, tannic acid, tellimagrandin II, terflavin B, or 3,4,5-tri-O-galloylquinic acid.

In some embodiments, the phenolic compound can be a flavonoid which includes several thousand natural phenol compounds. Examples of the flavonoids include the flavonols, flavones, flavan-3-ol (catechins), flavanones, anthocyanins, isoflavonoids, and hybrids of any combination of these compounds. In some embodiments, the phenolic compounds are the hydrolysable tannins such as, for example, gallic acid. In some embodiments, the phenolic compounds are the lignins such as, for example, astringinic acid. In some embodiments, the phenolic units can be dimerized or further polymerized to form any of a variety of hybrids. For example, ellagic acid is a dimer of gallic acid and forms the class of ellagittannins, or a catechin and a gallocatechin can combine to form theflavin or the large class of thearubigins found in tea. In another example, a flavonoid and a lignan can combine to form a hybrid, such as a flavonolignans.

In some embodiments, the phenolic compound can be a flavan-3-ol. Examples include the catechins and the catechin gallates, where the catechin gallates are gallic acid esters of the catechins. In some embodiments, the phenolic compound is a catechin or epicatechin compound (the cis- or transomers). In some embodiments, the phenolic compound is a (+)-epicatechin or (-)-catechin. In some embodiments, the phenolic compound is epigallocatechin (EGC) or gallocatechin (EC). In some embodiments, the phenolic compound is a catechin gallate, such as epigallocatechin gallate (EGCG).

In some embodiments, the phenolic compound can be selected from the group of flavones consisting of apigenin,
luteolin, tangeritin, flavonols, isorhamnetin, kaempferol, myricetin (e.g., extractable from walnuts), proanthocyanidins or condensed tannins, and quercitin and related phenolic compounds, such as rutin.

In some embodiments, the phenolic compound can be selected from the group of flavonoids consisting of eriodictyl, hesperetin (metabolizes to hesperidin), and naringenin (metabolized from narin). In some embodiments, the phenolic compound can be selected from the group of flavonoids consisting of catechin, gallocatechin and their corresponding gallate esters, epicatechin, epigallocatechin and their corresponding galicate esters, thealflavin and its galicate esters, thearubigins, isoflavone phytoestrogens (found primarily in soy, peanuts, and other members of the Fabaceae family), daidzein, genistein, glycitein, stilbenoids, resveratrol (found in the skins of dark-colored grapes, and concentrated in red wine), pterostilbene (methoxylated analogue of resveratrol, abundant in *Vaccinium* berries), anthocyanins, cyanidin, delphinidin, malvidin, pelargonidin, peonidin, and petunidin. And, in some embodiments, the phenolic compound can be ubiquinol an electron-rich (reduced) form of coenzyme Q10.

In some embodiments, the phenolic compound can be selected from the group of carotenoid terpenoid consisting of alpha-carotene, astaxanthin (found naturally in red algae and animals higher in the marine food chain, a red pigment familiarly recognized in crustacean shells and salmon flesh/roe), beta-carotene (found in high concentrations in butternut squash, carrots, orange bell peppers, pumpkins, and sweet potatoes), canthaxanthin, lutein (found in high concentration in spinach, kiwifruit and red peppers), lycopene (found in high concentration in ripe red tomatoes and watermelons) and zeaxanthin (the main pigment found in yellow corn, also abundant in kiwifruit).

In some embodiments, the phenolic compound can be selected from the group of polyphenolic acids and their esters consisting of chicoric acid (another caffeic acid derivative, is found only in the medicinal herb echinacea purpurea), chlorogenic acid (found in high concentration in coffee (more concentrated in robusta than arabica beans, blueberries and tomatoes, and produced from esterification of caffeic acid), cinnamic acid and its derivatives, such as ferulic acid (found in seeds of plants such as in brown rice, whole wheat and oats, as well as in coffee, apple, artichoke, peanut, orange and pineapple), ellagic acid (found in high concentration in raspberry and strawberry, and in ester form in red wine tannins), ellagitannins (hydrolysable tannin polymer formed when ellagic acid, a polyphenol monomer, esterifies and binds with the hydroxyl group of a polyol carbohydrate such as glucose), gallic acid (found in gallnuts, sumac, witch hazel, tea leaves, oak bark, and many other plants), gallotannins (hydrolysable tannin polymer formed when gallic acid, a polyphenol monomer, esterifies and binds with the hydroxyl group of a polyol carbohydrate such as glucose), rosmarinic acid (found in high concentration in rosemary, oregano, lemon balm, sage, and marjoram), and salicylic acid (found in most vegetables, fruits, and herbs; but most abundantly in the bark of willow trees, from where it was extracted for use in the early manufacture of aspirin).

In some embodiments, the phenolic compound can be selected from the group of nonflavonoid phenolics consisting of curcumin (has low bioavailability, because, much of it is excreted through glucuronidation, but bioavailability can be substantially enhanced by solubilization in a lipid (oil or lecithin), heat, addition of piperine, or through nanoparticles, in particularization, flavonolignans, for example, silymarin which is a mixture of flavonolignans extracted from milk thistle), eugenol and xanthones (mangoesteen, for example, is purported to contain a large variety of xanthones, some of which, like mangoestin are believed to be present only in the inedible shell).

In some embodiments, the phenolic compound can have a low molecular weight (less than about 400 Daltons), selected from the group consisting of caffeic acid, genistin acid, protocatechuic acid, phenylacetic acid, gallic acid, phloroglucinol carboxylic acid, and derivatives thereof. Such compounds can form a sufficiently soluble binding pair, and their relatively high hydroxyl group to molecular weight ratio creates favorable conditions for obtaining the intermolecular hydrogen bonds desired for the binding systems.

In some embodiments, the phenolic compounds can be from a natural extract, such as an extract of a plant or other natural product. See, for example, U.S. Published Patent Application Nos. 20100158885 and 20110070198, each of which is hereby incorporated by reference herein in its entirety. Those skilled in the art of such extracts will understand that extracts of plant materials are not typically pure in one type of phenolic compound. Plant tissue extracts, for example, typically comprise heterogenous mixtures and derivatives of the above classes.

One skill will appreciate, given the teachings provided herein, that the polyphenol can be combined with the reactive oxygen species as a component of a water or alcohol extract of a plant tissue. In some embodiments, the plant tissue can comprise a tannin or a pseudotannin. In some embodiments, the polyphenolic compound is extracted from a whole or partial plant tissue selected from the group consisting of seeds and fruits; ovaries; juice; pulp; gall; husks; bark; stems; leaves; flowers; sheaths; hulls; sprouts; bulbs; hips; tubers; roots of grains; grasses; legumes; trees; vegetables; medicinal herbs; tea leaves; algae; marine plants; and, fungi. One skill will appreciate that the type and content of phenolic compound obtained can be expected to vary with the species, season, geographical location, cultivation, and storage. Examples of plant tissues include, but are not limited to, plant tissues from the species of *Aloe, Pachyverea*, and *Opuntia*. Other examples can include, but are not limited to, *Aga- vaceaeeae, Caetaceaeeae, Pouaceaeeae, Theaceae*, *Leguminosae*, and *Lyracea*. In some embodiments, the plant tissues can be selected from the group consisting of pomegranate huck, *aloe vera* leaves, and green tea leaves. Other examples of plant tissues can include, but are not limited to *Aloe (Aloe vera), Angelica (Angelica archangelica), Barberry (Berberis vulgaris), Root Bark, Bilberry (Vaccinium myrtillus), Calendula (Calendula officinalis), Cramp bark (Viburnum opulus), Eleutherococcus root (Eleutherococcus senticosus), Kidney wood (Esenhardia orthotricha), Mimosa tenuiflora, Papaya (Carica papaya) leaves, Puya D’Are (Rabebeia avel- lanedae), Sassafras albidum root bark, Saw Palmetto (Serena repens), St. John’s wort (Hypericum perforatum), Valerian (Valeriana officinalis), Apple (Malus domestica), Grape (Vitis vinifera), Echinacea purpurea, Grape seed extract, and Blueberry (Vaccinium corymbosum)*. In some embodiments, the plant tissues are selected from the group consisting of barley germ, green tea leaves, *aloe vera* leaves, mung beans, carrot, cereal grains, seeds, buds, and sprouts.

Likewise, one skill will appreciate that there are numerous reactive oxygen species that can be used in the systems taught herein, as long as the reactive oxygen species function consistent with such teachings. Hydrogen peroxide, and precursors of hydrogen peroxide, are merely examples. In some embodiments, the polyphenolic compounds in the compositions (i) have phenolic hydroxyl groups that are oxidizable in the presence of a reactive oxygen species and an oxidoreductase
enzyme, and (ii) are soluble in a polar liquid, such as water or an alcohol, for example, or at least moderately soluble. The phenolic compounds should also be (iii) non-toxic to a subject upon administration. And, in some embodiments, the phenolic compounds should also (iv) crosslink or polymerize with itself or other phenolic compounds in the compositions taught herein.

The reactive oxygen species can be any such species known to one of skill to have the ability to combine with the polyphenol as a composition for the uses taught herein. For example, the reactive oxygen species can include, but is not limited to, the reactive oxygen species includes a component selected from the group consisting of hydrogen peroxide, superoxide anion, singlet oxygen, and a hydroxyl radical. In some embodiments, the reactive oxygen species comprises hydrogen peroxide. And, in some embodiments, the hydrogen peroxide can be combined with the tannin in a tannin: peroxide weight ratio that ranges from about 1:1000 to about 1:10. In some embodiments, the weight ratio of the tannin: peroxide ranges from about 1:1 to about 1:50. In some embodiments, the exogenous reactive oxygen species can be generated, as hydrogen peroxide for example, from a solid hydrogen peroxide generating material selected from the group consisting of sodium percarbonate, potassium percarbonate, a carbamide peroxide, and urea peroxide.

In some embodiments, the reactive oxygen species is hydrogen peroxide or materials that release or generate hydrogen peroxide including, but not limited to, hydration of adducts of hydrogen peroxide such as carbamide peroxide, magnesium peroxide, and sodium percarbonate; amino perhydrates; superoxide dismutase decomposition of ozone, superoxides or superoxide salts; glucose oxidase and glucose, aqueous dilution of honey; \( \text{H}_2\text{O}_2 \) production by \( \text{Lactobacillus} \); catalytic quinone hydrogenation; superoxides; and, superoxide dismutase. In some embodiments, the reactive oxygen species can include peroxide ion, organic peroxides, organic hydroperoxides, peroxides, superoxides, dioxygenyls, ozones, and oxonides. Hydrogen peroxide or materials that generate hydrogen peroxide can be obtained or derived synthetically or from plant tissues or combinations of plant tissues.

Enzymes can activate the compositions for the methods taught herein, and the systems for the methods of treatment can be designed accordingly. And, generally speaking, one of skill will appreciate that there are a wide variety of enzymes are possible and can be target site dependent. Generally, the enzymes fall into the classes of oxidoreductases. As such, there are several enzymes and isozymes that will be present at a target site and capable of bioactivating the binding systems. In some embodiments, the oxidoreductases can be categorized into about 22 classes, and the selectivity of the bioactivation of the binding system at a target site depends, at least in part, on the selectivity of the oxidoreductase at the target site. In some embodiments, the oxidoreductase can include those oxidoreductases that act on the C1—OH group of donors (alcohol oxidoreductases, for example; EC Number class 1.1). In some embodiments, the oxidoreductase can include those oxidoreductases that act on diphenols and related substances as donors (catechol oxidase, for example, EC Number class 1.10). In some embodiments, the oxidoreductase can include those oxidoreductases that act on peroxide as an acceptor (peroxidases, such as horseradish peroxidase and catalase; EC Number class 1.11). In some embodiments, the oxidoreductase can include those oxidoreductases that act on phenols as an acceptor (tyrosinases, for example; EC Number class 1.14). Examples of other useful enzymes for the teachings provided herein include, but are not limited to, glutathione peroxidase 1 and 4 (in many mammalian tissues), glutathione peroxidase 2 (in intestinal and extracellular mammalian tissues), glutathione peroxidase 3 (in plasma mammalian tissues), lactoperoxidase, myeloperoxidase (in salivary & mucosal mammalian tissues), myeloperoxidase (in neutrophil mammalian tissues), cytochrome peroxidase (in yeasts such as \( \text{Candida albicans} \)) and horseradish peroxidase (common to show in vitro activity).

One of skill will appreciate that oxidoreductases are selective and, in some embodiments, the oxidoreductase can include an alternate enzyme that are selective for a binding system having a phenolic compound that acts as a substrate for the alternative enzyme.

In some embodiments, the oxidoreductases include mono-oxygenases such as, for example, phenylalanine monoxygenase, tyrosine monoxygenase, and tryptophan monoxygenase. In some embodiments, the oxidoreductases include dioxigenases such as, for example, tryptophan dioxigenase, homogentisate dioxigenase, trimethyl lysine dioxigenase, and nitric oxide synthase. In some embodiments, the oxidoreductases include peroxidases such as, for example, catalase, myeloperoxidase, horseradish peroxidase. In some embodiments, the oxidoreductases act in the presence of a co-factor or co-enzyme, such as nicotinamide adenine dinucleotide phosphate (NADP) or nicotinamide adenine dinucleotide (NAD).

Methods of Making the Compositions
The design of the binding systems include (i) selecting the phenolic compound, (ii) selecting the reactive oxygen species, (iii) selecting the ratio of phenolic compound to reactive oxygen species, and (iv) selecting a carrier. In some embodiments, the phenolic compound can be derivatized or attached to another chemical moiety via a linker, or another known method such as, for example, esterification to facilitate or improve an association between the phenolic compound and the reactive oxygen species, as well as to potentially modify, solubility, tissue absorption, or toxicity.

One of skill will appreciate that, at least from the teachings provided herein, there are a vast number of components that can be selected, the selection of which is, at least in part, dependent on type of enzyme, co-enzymes, cofactors or catalysts present at the target site for the bioactivation of the system. The design of the system can include for example, (i) identifying the target site; (ii) identifying an enzyme, co-enzymes, cofactors or catalysts present at the target site but not present at tissue surrounding the target site; (iii) selecting a binding pair for activation at the target site by the enzyme, co-enzymes, cofactors, or catalysts; and, (iv) selecting a carrier in which the binding pair is stable or substantially stable. Identifying the target site can include, for example, select a target tissue for treatment, such as a staphylococcus tissue at which the enzyme, co-enzymes, cofactors or catalysts present. In some embodiments, the target site is a GI tissue, at which peroxidase or oxidase may be present. Identifying an enzyme, co-enzymes, cofactors, or catalysts present at the target site but not present at tissue surrounding the target site can include, for example, identifying the tissue type, as well as the presence of a microbe. Anaerobic pathogens such as \( \text{Pseudomonas} \) and \( \text{Vibrio} \), for example, can express a peroxide or an oxidase, making these enzymes available at the target site.

After the system and environment of use are known, one of skill can select a carrier in which the composition is stable or substantially stable. In one example, the binding system can comprise a mixture of phenolic compounds in a desired ratio with hydrogen peroxide. For example, the phenolic compounds can include a mixture of a pomegranate extract and a green tea extract, and the ratio of phenolic compound to hydrogen peroxide can range from about 1:2 to about 1:20 on
a wt/wt basis, which can include molar weight bases. In some embodiments, the hydrogen peroxide can be added to the phenolic compound using a concentration of about 0.01% to about 10% hydrogen peroxide solution, and any free hydrogen peroxide can remain or be removed using the teachings provided herein. One of skill can easily select the dose for a particular use, which will vary according to factors that include the environmental conditions at the site of use. In another example, the compositions can comprise a mixture of phenolic compounds in a desired ratio with hydrogen peroxide. For example, the phenolic compounds can include a mixture of a pomegranate extract and a green tea extract, and the ratio of phenolic compound to hydrogen peroxide can range from about 3:1 to about 1:3 on a wt/wt basis (e.g., molar weight). The hydrogen peroxide can be added to the phenolic compound using a concentration of about 0.01% to about 10% hydrogen peroxide. In some embodiments, a 35% hydrogen peroxide stock solution can be used as a source of hydrogen peroxide, which can be obtained from a commercially available stock solution, for example. In some embodiments, up to 60% hydrogen peroxide stock solution can be used as a source of hydrogen peroxide. In fact, higher concentrations are available, and could be used in some embodiments if handled properly. One of skill will be able to readily select, obtain and/or produce desired concentrations of hydrogen peroxide. Again, one of skill can easily select the dose for a particular use, which will vary according to factors that include environmental conditions at the site of use. In some embodiments, this formulation has worked well for uses in animals that are non-humans.

The compositions can include, for example, a weight (molar or mass) ratio of phenolic compound to reactive oxygen species that ranges from about 1:1000 to about 1000:1. In some embodiments, the ratio of phenolic compound to reactive oxygen species can range from about 1:1000 to about 500:1, from about 1:500 to about 500:1, from about 1:250 to about 500:1, from about 1:500 to about 250:1, from about 1:250 to about 250:1, from about 1:250 to about 250:1, from about 1:250 to about 250:1, from about 1:250 to about 250:1, from about 1:250 to about 250:1, from about 1:250 to about 250:1, from about 1:250 to about 250:1.

In some embodiments, the compositions comprise a ratio of a tannin and hydrogen peroxide, a phenylpropanoid and a hydrogen peroxide, a catechin and hydrogen peroxide, an epigallocatechin and a hydrogen peroxide, or a combination thereof of these phenolic compounds with hydrogen peroxide.

In some embodiments, the compositions include a stable hydrogen bonded complex between the phenolic compound and the reactive oxygen species. For example, a highly hydroxylated polyphenol compound can be combined with a high concentration of hydrogen peroxide, the combination leading to binding the hydrogen peroxide to the phenolic compound to produce the binding system. The binding system can be intended for dilution in water or a solid excipient.

One of skill will appreciate that such a complex can be referred to as a polyphenol peroxysolvate, in some embodiments, when in a liquid form for storage or administration to a subject, and a phenolic perhydrate when in an anhydrous, or substantially anhydrous, form for storage or administration to a subject.

The compositions can be carried in a liquid, powder, capsule, tablet, or gas for administration to a subject. The selection of the phenolic compound should take into consideration the manner in which the reactive oxygen species will bind to the phenolic compound to form a stable, or substantially stable, binding pair. The binding pair can be considered substantially stable where the reactive oxygen species retains all, most, or at least a predictable amount of oxidation strength for a time, and functions repeatedly.

One of skill will appreciate that a phenolic compound can be derivatized to introduce or enhance a desired function. The phenolic compound can be derivatized, for example, to increase its functionality for binding to the reactive oxygen species, maintaining stability or miscibility in a carrier, or binding to a target site, using any method known to one of skill. In some embodiments, the phenolic compound can be bound to a polyol, pegylated, attached to a saccharide, or attached to glucose, for example.

Moreover, one of skill will appreciate that the compositions should, in some embodiments, be produced free of compounds that can lead to degradation of the otherwise stable, or substantially stable, combinations. As such, in some embodiments, the compositions comprise solutes that are substantially free of transition metals, metal ions, heavy metals, oxidoreductase enzymes, other strong oxidizers, reactive halogen compounds, hydrogen halides, and other compounds that can cause a decomposition of the reactive oxygen species, or its dissociation from the phenolic compound with which it forms a binding pair.

The compositions can be made using ingredients from commercially available chemical providers, or they can be made directly from whole, plant extracts, for example, water extracts or alcohol extracts.

A Commercially Available Source of the Phenolic Component

Commercially available chemical providers, for example Sigma-Aldrich, can provide phenolic and polyphenolic chemicals for use with the methods of treatment taught herein. In the example set forth below, (i) gallic acid (a model polyphenol building block) is combined with hydrogen peroxide; and, (ii) tannic acid (a model polyphenol component) is combined with hydrogen peroxide. Both gallic acid and tannic acid are commercially available from Sigma-Aldrich. One of skill will appreciate that a wide variety of polyphenolics are commercially available.

A Whole, Plant Extract as a Source of the Phenolic Component

The method of obtaining the phenolic component, e.g., the polyphenol component, from a plant tissue can be produced using the following process:

i. Harvest plant tissue comprising a polyphenol component, for example, the polyphenol comprising a tannin. It is desirable to harvest while minimizing physical damage to the plant tissue. For example, whole leaf extractions can be performed to avoid physical damage to the leaves, but it may be desirable to reduce the size of the leaves by cutting them, for example, to increase the speed and yield of the extraction in some embodiments.
ii. Denaturing all, or substantially all, of the oxidoreductase enzymes in the plant. This can be done through drying, for example, using heating in the range of about 60°C to about 150°C, or a combination of such heating and dessication. Alcohol can also be used to denature the enzymes.

iii. Extracting the polyphenols from the plant tissue using a suitable solvent including, but not limited to, water or an alcohol. Water extractions have been used in this example. Since we’re after water soluble plant materials, a simple water extraction is sufficient to provide the plant extract containing polyphenols for the compositions.

The plant extraction procedures are simple, although they can be modified for efficiency in product yield and activity. Although inefficient, the simplest extraction procedure, for example, would be to merely harvest the plant tissue, denature the endogenous enzymes, and soak the tissue in water to isolate the water soluble extract of the plant tissue. Another simple extraction method would be to harvest the plant tissue, and isolate the water soluble extract of the tissue in water at temperatures greater than about 80°C to steam. An even simpler process would not include denaturing the enzymes, but the stability and activity of the extract in the composition suffers greatly. Additional steps can be added, however, to increase the efficiency of the extraction, although such steps are not required. For example, the harvesting can include cutting into as large of pieces as practical to the size of the plant to preserve the metabolic activity in the plant tissue can be done. The plant tissue can be pulverized after denaturing the enzymes, and the water can be heated at temperatures ranging from about 25°C to about 100°C, from about 30°C to about 95°C, from about 35°C to about 90°C, from about 40°C to about 85°C, from about 45°C to about 80°C, from about 50°C to about 75°C, from about 55°C to about 70°C, from about 65°C to about 65°C, or any amount or range therein in increments of 1°C, to make the process of extraction more efficient.

In some embodiments, the endogeneous enzymes include a catalase or peroxidase that is at least substantially inactivated. In some embodiments, the endogeneous enzymes can be inactivated through heating, cooling, boiling, freezing, dessicating, freezing and thawing cycles, blanching, or a combination thereof. In some embodiments, the endogeneous enzymes can be inactivated using a process that includes allowing natural degradation over time, adding at least 1% salt, radiating, or adding an exogenous chemical enzymatic inhibitor.

In some embodiments, the plant extract is produced from a process comprising: harvesting the plant tissue; at least partially inactivating an endogeneous enzyme; optionally reducing particle size of the plant tissue through cutting, avulsing, or pulverizing; creating the extracted component through a process that includes combining the plant tissue with water or alcohol for an effective time and at an effective temperature; optionally removing particles from the mixture; and, adding the reactive oxygen species to the effective, or otherwise desired amount.

In some embodiments, the water soluble plant extract can then be optionally filtered, for example, using a filter, for example a 5 µm filter in some embodiments, and hydrogen peroxide can then be added to the filtered extract to a concentration of 1% by weight of the total composition. In some embodiments, the hydrogen peroxide can be added to the extract in an amount ranging from about 0.01% to about 10% by weight of the total composition. Increasing the concentration of hydrogen peroxide added has been observed to increase the potency and stability of the resulting compositions.

After combining the reactive oxygen species with the polyphenol component, the free reactive oxygen species in the composition can be left in the composition, or it can be removed using an enzyme, catalyst, or reducing agent. In this example, the reactive oxygen species is hydrogen peroxide, and the free hydrogen peroxide can be removed from the composition in a subsequent step contacting the free hydrogen peroxide with a hydrogen peroxide degrading enzyme, such catalase; a catalyst such as manganese dioxide, platinum, iron, or copper; or, a reducing agent such as ferric chloride, copper sulfate, or sodium hypochlorite. In some embodiments, the composition having the free hydrogen peroxide can be contacted with a metal catalyst or catalase bound to a solid non-soluble substrate. In some embodiments, the solid substrate can be a bead column or screen, for example. Likewise, the catalysts and reducing agents can be used in a similar manner to remove the free hydrogen peroxide, or any other free reactive oxygen species.

As such, the concentration of free reactive oxygen species, such as free hydrogen peroxide, remaining in the composition can range from about 0 to about 10% based on total dry weight of the composition. Moreover, in some embodiments, the total hydrogen peroxide concentration can range from about 0.001% to about 1%, from about 0.01% to about 0.1%, from about 0.05% to about 0.5%, from about 0.005% to about 5%, from about 0.007% to about 2%, from about 0.01% to about 5%, from about 0.05% to about 5%, from about 0.1% to about 5%, from about 0.2% to about 4.5%, from about 0.3% to about 4%, from about 0.4% to about 3.5%, from about 0.5% to about 3%, from about 0.6% to about 2.5%, from about 0.7% to about 2%, from about 0.001% to about 1.5%, about 1%, or any amount or range therein in increments of 0.001%. And, it should be appreciated that the concentration of free hydrogen peroxide, for example, can also be reduced, or further reduced, by dilution of the composition in various commercial formulations.

Moreover, precipitates of protein or other impurities can form at this point and can optionally be removed by additional filtration, and we often filter after we allow the solution to react for about an hour. Although not necessary, additional reactive oxygen species can be added to ensure complete saturation of hydrogen peroxide on the binding sites of the polyphenols in the extract. In this example, hydrogen peroxide was used as the reactive oxygen species, keeping track of the total hydrogen peroxide concentration.

The plant extract is combined with the reactive oxygen species, and the solution can be allowed to react for a period of time ranging from about 10 minutes to about 72 hours, in some embodiments, before diluting the composition to a desired concentration. In some embodiments, the solution can be allowed to react for a period of time ranging from about 1 minute to about 96 hours, from about 5 minutes to about 48 hours, from about 10 minutes to about 36 hours, from about 10 minutes to about 24 hours, from about 10 minutes to about 12 hours, from about 10 minutes to about 8 hours, or from about 10 minutes to about 1 hour, or any range therein in increments of 1 minute. In this example, the extracts were allowed to react with the hydrogen peroxide for a minimum of 2 hours. The dilution can be desirable, for example, (i) to control the concentration of the composition in solution, and/ or (ii) to accelerate degradation of the unbound reactive oxygen species to limit the composition to having no, or substantially no, free reactive oxygen species. In this example, the hydrogen peroxide is more susceptible to degradation when
free in solution, and one of skill will appreciate that the degradation will increase in rate when the composition is diluted.

In some embodiments, dry compositions are provided. For example, the system can be in the form of a powder, pill, tablet, capsule, or as separate dry components for mixing into a liquid form. In these embodiments, both the phenolic compound and the reactive oxygen species are in a dry form either before or after creation of the binding pair, and the binding system can be used in the dry form, or converted to a liquid form, for any of the uses taught herein. The advantages of the dry compositions can include, for example, the ease of storage and transport. In some embodiments, the binding systems, whether in liquid or dry form, can be combined with vitamins, electrolytes, and/or other nutrients in either liquid or dry form. The dry form of the binding system can be manufactured using any drying process known to one of skill, such as solvent exchange, vacuum drying, critical point drying, heating, dessication, or a combination thereof. In some embodiments, the phenolic compound is dried as a single component. In some embodiments, the binding pair is formed, and the binding pair is dried together. And, in some embodiments, the reactive oxygen species can be, independently, in any dry form known to one of skill, such as the dry forms taught herein. In embodiments having the reactive oxygen species in an independent dry form, the dry phenolic compound and the dry reactive oxygen species can be combined in a polar solvent, for example, to create the binding pair prior to use.

Methods of Using the Compositions

Methods of treating gastrointestinal spasms are provided. This can include reducing or eliminating abdominal pain, bloating, forceful defection, forceful vomiting, defecation urgency, constipation, and/or incontinence. Causes of gastrointestinal cramping can range from mild conditions to serious conditions, such as food poisoning, constipation, gastroenteritis, viral infections, bacterial infections, lactose intolerance, excessive flatulence and bloating, indigestion, diverticulitis, autoimmune disease, intestinal inflammation and even colorectal cancer, adhesions, and the like. In some embodiments, stress and/or dehydration can even trigger gastrointestinal cramps, for example.

The disorders treated can be self-induced. In some embodiments, gastrointestinal spasms can be self-induced through overindulging, such as through overeating and/or overdrinking. In some embodiments, gastrointestinal spasms can be due to deficiencies, such as deficiencies in nutrition or hydration, for example. The compositions taught herein can be used in treating such conditions, either alone or in co-administrations with nutritional therapy or rehydration therapies. The disorders might also be induced through environmental conditions, exercise, or socioeconomic conditions. In some embodiments, the composition can be co-administered with at least one other nutritional and/or rehydrating agent for aiding recovery from a health imbalance, or to maintain a health balance. Examples of rehydrating agents can include, but are not limited to, GATORADE and other electrolyte drinks, oral rehydration solutions (ORSs) generally, new oral rehydration solution (N-ORS), SEURO ORAL, PEDIA-ONE, and PEDIALYTE. Examples of nutritional supplements can include, but are not limited to, vitamin sulfate, salted rice water, salted yogurt-based drinks, and vegetable or chicken soup with salt. Such health imbalances can include, but is not limited to, dehydration, malnutrition, electrolyte imbalance, vitamin deficiency, food hypersensitivities, stress induced diarrhea, abdominal cramping, and alcohol hangover, or a combination thereof. In some embodiments, the methods taught herein can further include the administration of oral rehydrating or nutritional agents such as sodium, potassium, dextrose, fructose, glucose, magnesium, zinc, selenium, vitamin A, Vitamin D, Vitamin C, dietary fiber, and combinations thereof. The amounts and ratios of the agents to the composition can be substantially varied to provide prophylaxis, therapy or maintenance of healthful balance. Ratios of the compositions herein to the nutritional agents or rehydration agents can range, for example, from about 1:100 to about 100:1, from about 1:50 to about 50:1, from about 1:40 to about 40:1, from about 1:30 to about 30:1, from about 1:20 to about 20:1, from about 1:10 to about 10:1, from about 1:5 to about 5:1, from about 1:4 to about 4:1, from about 1:3 to about 3:1, from about 1:2 to about 2:1, from about 1:1.5 to about 1.5:1, about 1:1, or any range therein. The ratios can be based on volume/volume, mass/volume, volume/volume, mass/volume, mass/molar. It should be appreciated that the concentrations of the compositions taught herein can be the same or different than the concentrations of the nutritional agents or rehydration agents. And, it should also be appreciated that the concentrations and ratios of concentrations can be subjective to a particular administration, such that they can be independently selected according to the condition treated, objective sought, desired effect, and/or personal preference. The combinations can be administered under any regime taught herein for the administration of an agent or combination of agents.

Irritable bowel syndrome (IBS) is a problem of particular interest and includes, for example, chronic or frequent gastrointestinal spasms. IBS is often diagnosed as a set of these symptoms, such as diarrhea, constipation, and bloating, in addition to, perhaps, a measured food sensitivity. The compositions taught herein, however, can generally be used for this and other medicinal purposes, as a health supplement, or a nutritional composition. The compositions can provide a therapeutic and/or prophylactic effect in the treatment of a condition in a subject, particularly in the treatment of a gastrointestinal spasm. The targeted action of the binding systems allows for the administration of surprisingly low effective doses of the phenolic compounds. As a result, the compositions also improve safety by substantially increasing the separation between an effective dose and any toxic side effects.

The terms “treat,” “treating,” and “treatment” can be used interchangeably and refer to the administering or application of the binding systems taught herein, including such administration as a health or nutritional supplement, and all administrations directed to the prevention, inhibition, amelioration of the symptoms, or cure of a condition taught herein. The terms “disease,” “condition,” “disorder,” and “ailment” can be used interchangeably in some embodiments. The term “subject” and “patient” can be used interchangeably and refer to an animal such as a mammal including, but not limited to, non-primates such as, for example, a cow, pig, horse, cat, dog, rat and mouse; and primates such as, for example, a monkey or a human. As such, the terms “subject” and “patient” can also be applied to non-human biologic applications including, but not limited to, veterinary, companion animals, commercial livestock, aquaculture, and the like. Many of the applications can include control environmental pathogens that are on or in plants, as well as places not necessarily in living hosts, such as those that are in water and water systems, for example, as well as soil, air, and food for microbial control, alteration of surface characteristics, or anywhere that can benefit from a supply of a stable oxidizer source.

In some embodiments, the composition includes (i) a phenolic compound selected from the group consisting of condensed tannins, hydrolysable tannins, complex tannins, phlo-
rotannins, psuedotannins, and derivatives thereof; and, (ii) hydrogen peroxide in a stable, or substantially stable, non-covalent association.

In some embodiments, the compositions taught herein can be used to protect, maintain, improve, or restore a digestive health of a subject when administered orally in an effective amount. In some embodiments, the effectiveness can be measured by comparing to a control group that did not receive the binding system. And, in some embodiments, the effectiveness can be measured according to a historical baseline for the subject being treated. The binding systems can be used to prevent, inhibit, or ameliorate the symptoms associated with a loss of digestive tract homeostasis. In some embodiments, the binding systems can be used to prevent, treat, ameliorate the symptoms of, or even cure, a chronic gastrointestinal condition. Such conditions can include, but are not limited to, hyperacidity, colitis, irritable bowel syndrome, crohn's disease, necrotic enteritis, functional colonic diseases, malabsorption, a peptic ulcer, gastro-esophageal reflux disease, ulcerative colitis, and diverticulitis. In some embodiments, the binding systems can be used to reduce mucosal tissue inflammation, dysfunction, or damage. Such conditions can be induced, for example, by drug side effects, chemotherapy, dysbiosis, radiation, changes in normal flora, hyperimmunity, autoimmune reactions, immune deficiencies, nervousness, allergies, chemical irritation, and stress. In some embodiments, the binding systems can be administered for selectively inhibiting the growth of gastrointestinal pathogens. It should be appreciated that there may be lesser inhibition of non-pathogenic strains, particularly common probiotic bacteria such as bifidobacteria and lactobacilli. And, in some embodiments, administration of the binding systems can produce short term immune modulation effects as well as potentially change the chronic expression of the activating enzymes associated with some conditions with longer term use of the binding systems.

In some embodiments, the symptoms of a gastrointestinal condition can include, for example, diarrhea, dehydration, malnutrition, constipation, nausea, and/or cramping. And, in some embodiments, the symptoms of a gastrointestinal condition can be temporary and include acid irritation, indigestion, diarrhea, constipation, gas, cramps, spasmodic peristalsis. Administering the binding systems for the treatment and/or management of gastrointestinal conditions can be considered a nutritional or health supplement, in some embodiments. In some such embodiments, for example, the binding pair can be administered to prevent, inhibit, or ameliorate the effect, infectivity, and virulence of pathogens including bacteria, viruses, fungi, yeasts, protozoa, and parasites. In a subject orally taking an effective amount of the supplement.

As described herein, the binding systems can be used in a method of treating acute diarrhea in a subject. In some embodiments, the method comprises orally administering an effective amount of a binding system taught herein to the subject. The binding system can prevent, inhibit, or ameliorate a symptom of acute diarrhea in the subject when compared to a second subject in a control group in which the binding system was not administered. In some embodiments, the symptom is selected from the group consisting of a stool score, heartburn, indigestion, urgency of defecation, nausea, vomiting, stomach pain, and bloating. As described herein, the binding systems can be used in a method of treating inflammatory bowel disease in a subject. In some embodiments, the method comprises orally administering an effective amount of a binding system taught herein to the subject. The binding system can prevent, inhibit, or ameliorate the symptoms of inflammatory bowel disease in the subject when compared to a second subject in a control group in which the binding system was not administered. In some embodiments, the symptom is selected from the group consisting of a stool score, heartburn, indigestion, urgency of defecation, nausea, vomiting, stomach pain, and bloating.

Methods of Administering the Compositions

The terms “administration” or “administering” can be used to refer to a method of incorporating a composition into the cells or tissues of a subject, either in vivo or ex vivo to test the activity of a system, as well as to diagnose, prevent, treat, or ameliorate a symptom of a disease. In one example, a compound can be administered to a subject in vivo using any means of administration taught herein. In another example, a compound can be administered ex vivo by combining the compound with cell tissue from the subject for purposes that include, but are not limited to, assays for determining utility and efficacy of a composition. And, of course, the systems can be used in vitro to test their stability, activity, toxicity, efficacy, and the like. When the compound is incorporated in the subject in combination with one or active agents, the terms “administration” or “administering” can include sequential or concurrent incorporation of the compound with the other agents such as, for example, any agent described above. A pharmaceutical composition of the invention can be formulated, in some embodiments, to be compatible with its intended route of administration.

Any administration vehicle known to one of skill to be suitable for administration of the compounds, compositions, and formulations taught herein can be used. A “vehicle” can refer to, for example, a diluent, excipient or carrier with which a compound is administered to a subject. A “pharmacologically acceptable carrier” is a diluent, adjuvant, excipient, or vehicle with which the composition is administered. A carrier is pharmaceutically acceptable after approval by a state or federal regulatory agency or listing in the U.S. Pharmacopeial Convention or other generally recognized sources for use in subjects. The pharmaceutical carriers include any and all physiologically compatible solvents, dispersion media, coatings, antibacterial and antifungal agents, isotonic and absorption delaying agents, and the like. Examples of pharmaceutical carriers include, but are not limited to, sterile liquids, such as water, oils and lipids such as, for example, phospholipids and glycolipids. These sterile liquids include, but are not limited to, those derived from petroleum, animal, vegetable or...
The compositions may be administered as suspensions or emulsions. Lipophilic solvents or vehicles include, but are not limited to, fatty oils such as, for example, sesame oil; synthetic fatty acid esters, such as ethyl oleate or triglycerides; and liposomes. Suspensions that can be used for injection may also contain substances that increase the viscosity of the suspension such as, for example, sodium carboxymethyl cellulose, sorbitol, or dextran. Optionally, a suspension may contain stabilizers or agents that increase the solubility of the compounds and allow for preparation of highly concentrated solutions. In some embodiments, an administration, such as an oral or rectal administration, for example, may include liposomes. In some embodiments, the liposome may assist in a targeted delivery system. The liposomes can be designed, for example, to bind to a target protein and be taken up selectively by the cell expressing the target protein.

In some embodiments, isotonic agents can be used such as, for example, sugars; polyalcohols that include, but are not limited to, mannitol, sorbitol, glycerol, and combinations thereof; and sodium chloride. Sustained absorption characteristics can be introduced into the compositions by including agents that delay absorption such as, for example, monosaccharide salts, gelatin, and slow release polymers. Carriers can be used to protect against rapid release, and such carriers include, but are not limited to, controlled release formulations in implants and microencapsulated delivery systems. Biodegradable and biocompatible polymers can be used such as, for example, ethylene vinyl acetate, polyanhydrides, polyglycolic acid, collagen, polyorthoesters, polyactic acid, polycaprolactone, polyglycolic copolymer, and the like. Such formulations can generally be prepared using methods known to one of skill in the art.

In some embodiments, the composition is administered in a sustained release formulation, and the formulation can include one or more agents in addition to the composition. In some embodiments, the sustained release formulations can reduce the dosage and/or frequency of the administrations of such agents to a subject. In some embodiments, an exogenous catalyst or enzyme is introduced to a target and one or more of the reactive oxygen species, phenolic compound, or the exogenous catalyst or enzyme are segregated by encapsulation or micellization to delay the bioactivation until target site is reached by all components.

One skill understands that the amount of the agents administered can vary according to factors such as, for example, the type of disease, age, sex, and weight of the subject, as well as the method of administration. For example, an administration can call for substantially different amounts to be effective. Dosage regimens may also be adjusted to optimize a therapeutic response. In some embodiments, a single bolus may be administered; several divided doses may be administered over time; the dose may be proportionally reduced or increased; or, any combination thereof, as indicated by the exigencies of the therapeutic situation and factors known one of skill in the art. It is to be noted that dosage values may vary with the severity of the condition to be alleviated, as well as whether the administration is prophylactic, such that the condition has not actually onset or produced symptoms. Dosage regimens may be adjusted over time according to the individual need and the professional judgment of the person administering or supervising the administration of the compositions, and the dosage ranges set forth herein are exemplary only and do not limit the dosage ranges that may be selected by medical practitioners. The compounds can be administered in dosage units. The term “dosage unit” can refer to discrete, predetermined quantities of a compound that can be administered as unitary dosages to
a subject. A predetermined quantity of active compound can be selected to produce a desired therapeutic effect and can be administered with a pharmaceutically acceptable carrier. The predetermined quantity in each unit dosage can depend on factors that include, but are not limited to, (a) the unique characteristics of the active compound and the particular therapeutic effect to be achieved, and (b) the limitations inherent in the art of creating and administering such dosage units.

An “effective amount” of a compound can be used to describe a therapeutically effective amount or a prophylactically effective amount. An effective amount can also be an amount that ameliorates the symptoms of a disease. A “therapeutically effective amount” can refer to an amount that is effective at the dosages and periods of time necessary to achieve a desired therapeutic result and may also refer to an amount of active compound, prodrug or pharmaceutical agent that elicits any biological or medicinal response in a tissue, system, or subject that is sought by a researcher, veterinarian, medical doctor or other clinician that may be part of a treatment plan leading to a desired effect. In some embodiments, the therapeutically effective amount should be administered in an amount sufficient to result in amelioration of one or more symptoms of a disorder, prevention of the advancement of a disorder, or regression of a disorder. In some embodiments, for example, a therapeutically effective amount can refer to the amount of an agent that provides a measurable response of at least 5%, at least 10%, at least 15%, at least 20%, at least 25%, at least 30%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 100% of a desired action of the composition.

In some embodiments, the desired action of the composition is relief of a gastrointestinal spasm. The relief can include, for example, reducing or eliminating abdominal pain, bloating, forceful defecation, forceful vomiting, defecation urgency, constipation, and/or incontinence. In these embodiments, at least 10% relief can be obtained in a time ranging from 1 minute to 24 hours, from about 5 minutes to about 18 hours, from about 10 minutes to about 12 hours, from about 20 minutes to about 8 hours, from about 30 minutes to about 6 hours, from about 1 hour to about 4 hours, from about 2 hours to about 10 hours, from about 3 hours to about 9 hours, or any range or amount therein in increments of 5 minutes.

A “prophylactically effective amount” can refer to an amount that is effective at the dosages and periods of time necessary to achieve a desired prophylactic result, such as prevent the onset of an inflammation, allergy, nausea, diarrhea, infection, and the like. Typically, a prophylactic dose is used in a subject prior to the onset of a disease, or at an early stage of the onset of a disease, to prevent or inhibit onset of the disease or symptoms of the disease. A prophylactically effective amount may be less than, greater than, or equal to a therapeutically effective amount.

In some embodiments, a therapeutically or prophylactically effective amount of a composition may range in concentration from about 0.01 nM to about 0.1 M; from about 0.01 nM to about 0.5 M; from about 0.1 nM to about 150 nM; from about 0.1 nM to about 1000 nM; from about 0.1 nM to about 1000 nM, 0.001 μM to about 0.1 M; from about 0.001 μM to about 0.5 μM; from about 0.01 μM to about 150 μM; from about 0.01 μM to about 500 μM; from about 0.01 μM to about 1000 μM; or any range therein. In some embodiments, the compositions may be administered in an amount ranging from about 0.005 mg/kg to about 100 mg/kg; from about 0.005 mg/kg to about 400 mg/kg; from about 0.01 mg/kg to about 300 mg/kg; from about 0.01 mg/kg to about 250 mg/kg; from about 0.1 mg/kg to about 200 mg/kg; from about 0.2 mg/kg to about 150 mg/kg; from about 0.4 mg/kg to about 120 mg/kg; from about 0.15 mg/kg to about 100 mg/kg; from about 0.15 mg/kg to about 50 mg/kg; from about 0.5 mg/kg to about 10 mg/kg, or any range therein, wherein a human subject is often assumed to average about 70 kg.

The amount of the composition administered may vary widely depending on the type of formulation, size of a unit dosage, kind of excipients, and other factors well known to those of ordinary skill in the art. A formulation may comprise, for example, an amount of the composition ranging from about 0.0001% to about 6% (w/w), from about 0.01% to about 1%, from about 0.1% to about 0.8%, or any range therein, with the remainder comprising the excipient or excipients. In some embodiments, the compositions can be administered, for example, in an amount of ranging from about 0.1 μg/kg to about 1 μg/kg, from about 0.5 μg/kg to about 500 μg/kg, from about 1 μg/kg to about 250 μg/kg, from about 1 μg/kg to about 100 μg/kg, from about 1 μg/kg to about 50 μg/kg, or any range therein. One of skill can readily select the frequency and duration of each administration. For example, depending on the gastrointestinal disorder treated, whether a prophylactic treatment or a treatment of an existing disorder, variables such as the age and size of the subject can be considered, as well as the source and type of the polyphenol component and the intensity of the symptoms. In these embodiments, the compositions can be administered orally in daily dosages ranging from about 5 μg to about 5000 μg dry weight, for example. In such embodiments, the compositions can be administered orally in amounts ranging from about 5 μg to about 5000 μg, from about 10 μg to about 4000 μg, from about 20 μg to about 3000 μg, from about 50 μg to about 2000 μg, from about 100 μg to about 1000 μg, from about 250 μg to about 500 μg, or any range therein, in dry weight. In some embodiments, the compositions can be administered orally in daily dosages of about 100 μg, about 200 μg, about 300 μg, about 400 μg, about 500 μg, about 600 μg, about 700 μg, about 800 μg, about 900 μg, about 1000 μg, about 2000 μg, about 3000 μg, about 4000 μg, about 5000 μg, about 6000 μg, about 7000 μg, about 8000 μg, about 9000 μg, or any range therein in increments of 50 μg dry weight.

In some embodiments, the composition can be administered in conjunction with at least one other therapeutic agent for the condition being treated. The amounts of the agents can be reduced, even substantially, such that the amount of the agent or agents desired is reduced to the extent that a significant response is observed from the subject. A significant response can include, but is not limited to, a reduction or elimination of nausea, a visible increase in tolerance, a faster response to the treatment, a more selective response to the treatment, or a combination thereof. In some embodiments, the methods taught herein can further include the administration of an antibiotic, an anti-emetic, an anticholinergic, an antispasmodic, or an anticancer agent.

Antibiotics can include, for example, aminoglycosides, ansamycins, carbacephem, carbapenems, cephalosporins (first through fifth generation), glycopeptides, lincosamides, macrolides, monobactams, penicillins, penicillin combinations, poly peptide, quinolones, sulfonamides, tetracyclines, and drugs against mycobacteria. In some embodiments, the antibiotic is selected from the group consisting of natural penicillin, cephalosporin, amoxicillin, ampicillin, clavamox, polymyxin, tetracycline, chlorotetracycline, doxycycline, chloramphenicol, erythromycin, oleandomycin, streptomycin, gentamicin, kanamycin, tobramycin, nalidixic acid,
rifampinc, rifampicin, proaol, ga:rnisil, trimethoprim, iso-
زيد, 7:1, from about 1:1 to about 1:1.8, from about 1:1 to
5  about 1:20;1, from about 1:1 to about 1:10.1, from about 1:5
to about 5:1, from about 1:4 to about 4:1, from about 1:3
to about 3:1, from about 1:2 to about 2:1, from about 1:5 to
10  about 1:5:1, about 1:1, or any range therein. The ratios can be
based on volume:volume, mass:volume, volume:mass, mass:
mass, or molar:molar. It should be appreciated that the con-
centrations of the compositions taught herein can be the same or
different than the concentrations of the nutritional agents or
rehydration agents. And, it should also be appreciated that the
concentrations and ratios of concentrations can be subjective
to a particular administration, such that they can be indepen-
dently selected according to the condition treated, objective
sought, desired effect, and/or personal preference. The com-
bined compositions can be administered under any regime taught herein for
the administration of an agent or combination of agents.

Articles of Manufacture

Articles of manufacture that encompass finished, packaged
and labelled products are provided. The articles of manufac-
ture include the appropriate unit dosage form in an appropri-
ate vessel or container such as, for example, a glass vial or
other container that is hermetically sealed. In the case of
dosage forms suitable for oral administration, the active
ingredient, e.g. one or more agents including a dosage form
taught herein, may be suitable for administration orally, rect-
tally, or the like.

As with any such product, the packaging material and
container are designed to protect the stability of the product
during storage and shipment. In addition, the articles of
manufacture can include instructions for use or other infor-
mation material that can advise the user such as, for example,
a physician, technician or patient, regarding how to properly
administer the composition as a prophylactic, therapeutic, or
ameliorative treatment of the disease of concern. In some
embodiments, instructions can indicate or suggest a dosing
regimen that includes, but is not limited to, actual doses and
monitoring procedures.

In some embodiments, the articles of manufacture can
comprise one or more packaging materials such as, for
example, a box, bottle, tube, vial, container, sprayer, insul-
fllator, intravenous (I.V.) bag, envelope, and the like; and at
least one unit dosage form of an agent comprising an extract
taught herein within the packaging material. There can be
a first composition comprising at least one unit dosage form of
an agent comprising a binding system as taught herein within
the packaging material, and optionally, a second composition
comprising a second agent such as, for example, any other
bioactive agent that may be administered in combination with
the binding system, or any prodrugs, codrugs, metabolites,
analogs, homologues, congeners, derivatives, salts, solvtes,
and combinations thereof. In some embodiments, the articles
of manufacture may also include instructions for using the
composition as a diagnostic, prophylactic, therapeutic, or
ameliorative treatment for the condition of concern. In some
embodiments, the instructions can include informational
material indicating how to administer the systems for a par-
ticular use or range of uses, as well as how to monitor the
subject for positive and/or negative responses to the systems.

In some embodiments, the article of manufacture can
include a substantially anhydrous binding system. For
example, a kit can be assembled which includes the anhy-
drous binding system comprising an anhydrous tanin with
instructions combining the tanin with and an anhydrous
reactive species generating component that forms a therapeutically, prophylactically, or nutritionally useful composition upon hydration.

Kits for the treatment of gastrointestinal spasms are provided herein. In these embodiments, the kits can include the polyphenol component and/or the reactive oxygen species in a wet or dry form. Optionally, the kits can include instructions for use in treating a subject. The instructions can include, for example, instructions on diluting the composition to a desired concentration and administration according to suggested dilution factors on the basis of ages and weights of subjects, as well as known conditions and target sites. The suggested dilution factors can be selected from the ranges taught herein. In some embodiments, the kits comprise a dry, stable form of the composition components. For example, the kits can comprise a dry form of a polyphenol component, such as one polyphenol, a combination of polyphenols, or an extract of a plant tissue having polyphenols. Moreover, the kits can also comprise a dry form of a hydrogen peroxide generating material that functions to generate an effective amount of an exogenous reactive oxygen species, wherein the reactive oxygen species includes a component selected from the group consisting of hydrogen peroxide, superoxide anion, singlet oxygen, and a hydroxyl radical. In these embodiments, the composition can be at least substantially free of active endogeneous oxidative enzymes and catalytic substances that cause degradation of the composition.

Example 1

Making and Testing an Antispasmodic Composition

This experiment includes the use of gallic acid, tannic acid, a pomegranate husk extract, and a green tea extract.

Measuring the Amount of Hydrogen Peroxide that Remains Bound to the Polyphenol

One of skill knows that hydrogen peroxide does not exist in a pure, solid form under normal conditions, for example, ambient conditions. However, this example shows that the hydrogen peroxide can exist in dry form when in association with the model compounds and plant extracts, and the compositions have been isolated in a dry form as proof. Art-recognized procedures, such as those set-forth at least in U.S. Patent Nos. 3,860,694; 3,864,454; 4,171,280; and 4,966,762, were used as a guide for this study.

The model compounds were used to show that the compounds include hydrogen peroxide, the reactive oxygen species component, in a relatively stable association with the polyphenol component. As discussed, one of skill will appreciate that hydrogen peroxide in a free form, for example, would otherwise quickly degrade. The polyphenols were provided from model compounds or plant extracts. A dry form of the compositions was made between (i) gallic acid (a model polyphenol building block) and hydrogen peroxide; (ii) tannic acid (a model polyphenol component from Sigma-Aldrich) and hydrogen peroxide; (iii) pomegranate husk extract and hydrogen peroxide; and, (iv) green tea extract and hydrogen peroxide, using the procedures taught herein, including:

i. adding a solution of 35% hydrogen peroxide slowly into each of the gallic acid powder, tannin powder, pomegranate husk extract powder, or green tea extract powder. The adding is done in a glass dish or beaker at 45-65° C. under constant, gentle mixing;

ii. creating a dry form of the composition by continuing the heating under the constant, gentle mixing until fine dry granules or hard amorphous chunks form;

iii. crushing the granules or chunks into a powder, which is the dry form; dissolving the powder into water, knowing that the dry forms will not have stable, free hydrogen peroxide, such that the dissolved powder will carry only the stabilized hydrogen peroxide associated with the model compounds or extracts; and,
iv. measuring the total hydrogen peroxide concentration associated with the model compounds or extracts in the dry form.

The hydrogen peroxide concentration measurements were taken using standard methods to determine the amount of hydrogen peroxide that bound to the model compounds or extracts in the dry form. It was found that (i) about 3.0% hydrogen peroxide bound to the gallic acid (a model polyphenol building block) by total dry wt; (ii) about 2.5% hydrogen peroxide bound to the tannic acid (a model polyphenol component) by total dry wt; (iii) about 1.8% hydrogen peroxide bound to the pomegranate husk extract by total dry wt; and, (iv) about 2.0% hydrogen peroxide bound to the green tea extract by total dry wt. To measure the hydrogen peroxide levels, a standard, WATERWORKS peroxide test strip method was used having a test sensitivity of 0.5, 2, 5, 10, 25, 50, 100 ppm, available from Industrial Test Systems, Inc., Rock Hill, S.C. 29730.

FIGS. 1A-1H are photographs of the dry forms of (A) gallic acid (a model polyphenol building block) bound to hydrogen peroxide; (B) gallic acid alone; (C) tannic acid (a model polyphenol) bound to hydrogen peroxide; (D) tannic acid alone; (E) pomegranate husk extract bound to hydrogen peroxide; (F) pomegranate husk extract alone; (G) green tea extract bound to hydrogen peroxide; and (H) green tea extract alone, according to some embodiments. As can be seen, the dry compositions exist and do contain a stable amount of hydrogen peroxide in an amount ranging from about 1.8% to about 3.0%, indicating the stabilizing association between the combined model compounds and extracts with the hydrogen peroxide. One of skill will appreciate that, surprisingly, the compositions contain a substantial amount of a stabilized hydrogen peroxide that is carried with the model compounds or extracts in a dry form.

The Stability of the Hydrogen Peroxide in the Combination is Greater in an Aqueous Solution than the Stability of the Hydrogen Peroxide Alone in the Aqueous Solution

This method tests the stability of the hydrogen peroxide in the combination. The testing methods used follow the standard procedures set-forth by the Clinical and Laboratory Standards Institute (CLSI) and US Pharmacopeia.

i. E. coli was chosen as the bacteria to challenge the stability of the bound compositions and the free hydrogen peroxide.

ii. The hydrogen peroxide concentration was matched to the selected bacteria in order to form a useful curve representing hydrogen peroxide degradation over time for the samples. As such, the hydrogen peroxide was varied from 62.5 ppm to 500 ppm on a fixed E. coli concentration of 10⁶ CFU/mL, and a concentration of 125 ppm was chosen as the initial hydrogen peroxide level used to challenge the E. coli over time.

iii. A ratio of 1:1 of the hydrogen peroxide to each of the model compounds and plant extracts was used to form each bound composition, such that 125 ppm of each plant extract was combined with the 125 ppm of the hydrogen peroxide.

iv. The free hydrogen peroxide was added at a concentration of 125 ppm as a control to show the relative stability of the hydrogen peroxide alone in the aqueous solution as compared to the bound compositions.

v. The samples were tested using the following methods:

   a. E. coli concentration was 10⁶ CFU/mL.
   b. The hydrogen peroxide concentration was varied from 62.5 ppm to 500 ppm on a fixed E. coli concentration of 10⁶ CFU/mL.
   c. The samples were incubated at 37°C for 24 hours.
   d. The concentration of hydrogen peroxide was measured using the WATERWORKS peroxide test strip method.

vi. The results showed that the hydrogen peroxide concentration in the combination was significantly higher than the hydrogen peroxide concentration in the free form.
FIGS. 2A and 2B show that the stability of the hydrogen peroxide in the combination is consistently, substantially greater in an aqueous solution than the stability of the hydrogen peroxide alone in the aqueous solution, according to some embodiments. FIG. 2A compares stabilities of free hydrogen peroxide to hydrogen peroxide bound to each of: gallic acid (a model polyphenol building block), tanic acid (a model polyphenol), pomegranate husk extract, green tea extract, and Blessed thistle extract. FIG. 2B shows very similar and consistent stabilities when comparing free hydrogen peroxide to hydrogen peroxide bound to a wide variety of species of plants: Aloe, Angelica, Barberry Root Bark, Bilberry, Calendula, Cranberry, Eleutherococcus root, Kidney wood, Mimosa tenuiflora, Papaya leaves, Pau D’Arco, Sassafras albidum root bark, Saw Palmetto, St. John’s wort, Valerian, Apple, Grape, Echinacea purpurea, Grape seed extract, and Blueberry. In both FIGS. 2A and 2B, there are curves that cannot be identified well individually, as they are identical and overlapping. The free hydrogen peroxide curve does not overlap with any of the bound compositions beyond the 4 hour mark. Table 1 provides data used to produce the curves in the overlap for clarity.

The results were quite impressive and surprising, as the free hydrogen peroxide degraded quickly to near 0.0 ppm each time within about the first 8 hours, whereas each of the bound compositions maintained at least 10 ppm or greater for the total duration of the study, which was limited due to time constraints. As such, it was observed that the stabilities were maintained at a concentration of at least 10 ppm or greater for at least 24 hours, a concentration sufficient to maintain bactericidal activity in water. FIG. 2A shows that at least 7 days of stability remained present in at least the samples that were afforded at the least 7 days of testing. In fact, potencies have been observed to remain in the compositions when challenged for at least 30 days, and the original batches have shown to remain potent for at least 90 days, in some cases.

Example 2

Treating Gastrointestinal Spasms in Patients Having Irritable Bowel Syndrome

A physician-controlled, open-label pilot study of 29 patients was performed. The patients suffered chronic gastrointestinal symptoms, including gastrointestinal spasms, and were selected because they were either non-responsive, or merely partially responsive, to standard treatments. The patients had been diagnosed with irritable bowel syndrome (IBS) and ranged in age from 29 years old to 79 years old, having a mean age of 51 years old. 83% of the patients were female. The patients were provided with sufficient volume of the composition for five days of consumption and asked to note any response or effects of the extract. Each of the patients received a 25 ml bottle of the test composition and instructed to take 5 ml per day with water at least 1 hour before meals for a 5 day period. The patients had been under treatment for chronic GI distress for an extended period and were asked to compare the performance of the test composition against their own subjective baseline health.

The Test Composition

The test solution ("the composition" or "the test composition") contained approximately 1100 micrograms total dry weight of desiccated pomegranate and green tea extract dissolved in a solution of 0.05% hydrogen peroxide in purified water. 25 ml was of the solution was then further diluted in 250 ml of oral rehydration solution to a final concentration of 0.0045% hydrogen peroxide and 100 micrograms of polyphenols before administration. Unused and undiluted solutions of the composition from the same lot were tested for hydrogen peroxide concentration using standard methodologies, described herein, verifying an unchanged ratio of peroxide to polyphenols. The free hydrogen peroxide at the fully diluted oral concentration was well below its conventionally accepted minimum inhibitory concentration for most bacteria.

The composition was tested for stability. Consistent with the methods taught herein, the composition was dessicated to a gummy solid with slow heating in a glass dish or beaker at 45-65°C under constant, gentle mixing, along with vacuum dessication to degrade free hydrogen peroxide. The composition was then rehydrated to its original liquid volume to determine the amount of hydrogen peroxide that was stable enough to remain in the composition. And, to compare the composition to those prepared from other plant tissues, the same test was performed with a variety of polyphenol extracts including grape skin extract, guava leaf extract, green tea extract only, pomegranate rind only, Aloe vera skin extract, and knotweed extract. All of the compositions retained a substantial concentration of a stable, hydrogen peroxide through the dessication and rehydration cycle, providing evidence that water extracts from different plant sources provide a source of polyphenols that form similar stable compositions with hydrogen peroxide.

The study

Significant responses to administration of the composition were observed. Of the 29 patients, 4 complained of constipation and 2 showed improvement. The 6 out of the 13 with gluten sensitivity (a test used in the diagnosis of IBS) reported reduced incidence of bloating, abdominal pain, bowel urgency or soft/water stools following gluten intake, suggesting that the composition is an effective treatment for irritable bowel syndrome. 19 out of the 29 (65%) subjects generally reported an improved health and relief of symptoms. 11 out of 16 (69%) of the subjects, a rather high percentage, reported improvement in gastrointestinal spasm symptoms. It has been observed, generally, that subjects receiving the composition have reported significant improvements over their historic baseline health within 24 hours.

A literature comparison

As described above, loperamide can be used to treat symptoms of IBS. As an agent for IBS patients, loperamide has

In comparison, the results to date suggest that the compositions taught herein offer a significant improvement over the results that have been observed in the literature for loperamide, for example, at least with regard to the treatment of IBS.

Other Studies

Other compositions using polyphenols derived from water extractions from other plants have been tested and shown to provide similar results. In one study, grape skin extract and guava leaf extract have been combined with commercial food grade hydrogen peroxide and plant extracted hydrogen peroxide from aloevera gel. This composition was administered to human subjects suffering from abdominal cramps. In all cases, the administration provided effective relief, evidence that other sources of water soluble polyphenol extracts provide commercially valuable and effective antispasmodic compositions.

In another study, 46 adults (including 6 having IBS) experiencing vomiting, abdominal pain, cramps, and bloating were given the 25 ml solution of the combination of composition (green tea/pomegranate/H2O2) and reported near-immediate relief with a significant reduction in symptoms remaining after 24 hours of treatment when compared to a placebo group. 78% reported significant benefit.

Example 3

Prophylactic Inhibition or Prevention of Alcohol Overindulgence

Experimental prophylactic use of the compositions has shown in a variety of subjects that it can inhibit or prevent gastrointestinal symptoms of the over consumption of alcohol. Surprisingly, it was also effective at inhibiting or preventing other symptoms of excess alcohol consumption. For example, the symptoms that have been prevented or inhibited have been measured against the historic baseline of the subject, including an alcohol-induced headache; and, alcohol-induced dander and other tissue reactions such as apparent immune-type, allergic reactions that included itchiness, blotchiness, flushing, red eyes, and runny nose.

Prior to the consumption of alcohol at a social event, each of the subjects consumed approximately 2000 ug-5000 ug of a green tea/pomegranate composition (dry weight) with water. The green tea/pomegranate that was administered was from a variety of lots and varied in ratio from 1:1 to 4:1 wt/wt. The subjects consumed approximately 2-10 alcoholic drinks, mixed and/or straight, ranging in content from about 5% to about 60% alcohol. The drinks ranged in content from wine to beer to liqueurs to liquors, and combinations thereof. Each of the subjects expressed that the composition provided a substantial prophylactic effect to inhibit or prevent the effects of the alcohol consumption, using their own, personal historic baselines of what they expected to experience without consuming the composition prior to drinking.

The experiments shown herein are for illustration and example only. One of skill can vary the experimental conditions and components to suit a particular or alternate experimental design. The experimental conditions can be in vitro or in vivo, or designed for any subject, for example, human or non-human. For example, animal testing can be varied to suit a desired experimental method. As such, one of skill will appreciate that the concepts can extend well-beyond the examples shown, a literal reading of the claims, the inventions recited by the claims, and the terms recited in the claims.

We claim:

1. A method of treating a gastrointestinal spasm associated with malnutrition in a subject, the method comprising: administering an effective amount of a composition to a subject having malnutrition with an associated gastrointestinal spasm, the composition having a water soluble polyphenol that was (i) water-extracted from a mixture of pomegranate husk and green tea leaf and (ii) combined with hydrogen peroxide prior to the administering; wherein, the hydrogen peroxide concentration ranges from about 0.001% to about 2.0% based on total dry weight of the composition; the polyphenol comprises a tannin; the polyphenol has a molecular weight ranging from about 170 Daltons to about 4000 Daltons; and, the composition relieves the malnutrition in the subject by relieving the associated gastrointestinal spasm when compared to a second subject in a control group also having malnutrition with an associated gastrointestinal spasm in which the composition was not administered.

2. The method of claim 1, further comprising adding a nutritional supplement selected from the group consisting of sodium, potassium, dextrose, fructose, glucose, magnesium, zinc, selenium, Vitamin A, Vitamin D, Vitamin C, dietary fiber, and combinations thereof.

3. The method of claim 1, wherein the hydrogen peroxide concentration ranges from about 0.001% to about 1.5% based on total dry weight of the composition.

4. The method of claim 1, wherein the hydrogen peroxide concentration ranges from about 0.001% to about 1.0% based on total dry weight of the composition.

5. The method of claim 1, wherein the relief of the spasm is measured using a response selected from the group consisting of a reduction in abdominal pain, a reduction in bloating, a reduction in forceful defecation, a reduction in forceful vomiting, a reduction in defecation urgency, a reduction in constipation, and a reduction in incontinence.

6. The method of claim 1, wherein the polyphenol comprises a hydrolysable tannin.

7. The method of claim 1, wherein the polyphenol comprises a hydrolysable tannin.

8. The method of claim 1, wherein the polyphenol comprises a combination of a hydrolysable tannin and a water soluble condensed tannin.

9. The method of claim 1, wherein the polyphenol comprises a flavanol.

10. The method of claim 1, wherein the polyphenol comprises a catechin.

11. The method of claim 1, wherein the polyphenol comprises gallic acid, epigalllic acid, or a combination thereof.

12. The method of claim 1, wherein the composition is administered in combination with an oral hydration solution.

13. The method of claim 1, wherein the polyphenol an ellagitannin and a gallotannin.
14. The method of claim 1, wherein the polyphenol includes a punicalagin.

15. A method of treating a gastrointestinal spasm associated with malnutrition in a subject, comprising:
administering an effective amount of a composition to a subject having malnutrition with an associated gastrointestinal spasm, the composition produced from a process including
extracting a water soluble polyphenol from a combination of green tea leaf and pomegranate husk;
combining the polyphenol with hydrogen peroxide prior to the administering; wherein, the polyphenol has a molecular weight ranging from about 170 Daltons to about 4000 Daltons;
selecting a desired concentration for the composition; and,
diluting the composition to the desired concentration for the administering;
wherein,
the hydrogen peroxide concentration ranges from about 0.001% to about 2.0% based on total dry weight of the composition;
the polyphenol comprises a tannin; and,
the composition relieves the malnutrition in the subject by relieving the associated gastrointestinal spasm when compared to a second subject in a control group also having malnutrition with an associated gastrointestinal spasm in which the composition was not administered.

16. The method of claim 15, further comprising adding a nutritional supplement selected from the group consisting of sodium, potassium, dextrose, fructose, glucose, magnesium, zinc, selenium, Vitamin A, Vitamin D, Vitamin C, dietary fiber, and combinations thereof.

17. The method of claim 15, wherein the hydrogen peroxide concentration ranges from about 0.001% to about 1.5% based on total dry weight of the composition.

18. The method of claim 15, wherein the hydrogen peroxide concentration ranges from about 0.001% to about 1.0% based on total dry weight of the composition.

19. The method of claim 15, wherein the relief of the spasm is measured using a response selected from the group consisting of a reduction in abdominal pain, a reduction in bloating, a reduction in forceful defecation, a reduction in forceful vomiting, a reduction in defecation urgency, a reduction in constipation, and a reduction in incontinence.

20. The method of claim 15, wherein the polyphenol comprises a hydrolysable tannin.

21. The method of claim 15, wherein the polyphenol comprises a water soluble condensed tannin.

22. The method of claim 15, wherein the polyphenol comprises a combination of a hydrolysable tannin and a water soluble condensed tannin.

23. The method of claim 15, wherein the polyphenol comprises a flavanol.

24. The method of claim 15, wherein the polyphenol comprises a catechin.

25. The method of claim 15, wherein the polyphenol comprises gallic acid, epigallocatechin, or a combination thereof.

26. The method of claim 15, wherein the polyphenol includes an ellagitanin and a gallotannin.

27. The method of claim 15, wherein the polyphenol includes a punicalagin.

28. A method of treating a gastrointestinal spasm associated with malnutrition in a subject, comprising:
administering an effective amount of a composition to a subject having malnutrition with an associated gastrointestinal spasm, the composition produced from a process including
obtaining a water extract from a green tea leaf and a water extract from a pomegranate husk;
combining the water extract from the green tea leaf and the water extract from the pomegranate husk to form a mixture of polyphenols having a molecular weight ranging from about 170 Daltons to about 4000 Daltons; and,
adding hydrogen peroxide to the polyphenol prior to the administering, the hydrogen peroxide concentration selected from a group consisting of concentration ranges from about 0.001% to about 2.0%, from about 0.001% to about 1.5%, from about 0.001% to about 1.0%, and from about 0.001% to about 0.1%, each range based on total dry weight of the composition;
wherein,
the polyphenol comprises a tannin; and,
the malnutrition in the subject by relieving the associated gastrointestinal spasm when compared to the baseline health of the subject prior to the administering.
